AI JOB HUNT TRACKER

AI-Assisted Job Application Data Analytics Report

1. Project Overview

This project analyses a sample dataset of 10 job application records. Excel was used to store the records, Python and SQL for data preparation and analysis, and Power BI for an interactive dashboard. Google Gemini AI was separately given summarized dataset information to generate written observations and suggestions.

2. Dataset Snapshot

Metric	Value
Total applications	10
Applied	5 (50%)
Interview status	3 (30%)
Rejected	1 (10%)
Offer	1 (10%)
Average salary shown in dashboard	5.35 LPA
Interview records / rounds	4

The 30% Interview Rate represents 3 applications marked 'Interview' out of 10. The separate Total Interviews card shows 4 interview records/rounds, which is a different measure and should not be interpreted as 4 distinct applications.

3. Job Portal Distribution

The sample contains 4 applications from LinkedIn, 3 from Naukri, 2 from company websites and 1 from Indeed. LinkedIn has the highest application count in this sample. This count alone does not prove that LinkedIn performs best; that comparison would require portal-specific outcome rates and a larger dataset.

4. What the Power BI Dashboard Shows

- Application status distribution: Applied, Interview, Offer and Rejected.
- Application counts by job portal.
- Average salary by company.
- Application locations and work-mode filtering.
- Summary KPIs such as total applications, interview rate and offers.

5. Role of Google Gemini AI

Python created summaries of the job application dataset and sent them to Google Gemini through the Gemini API with a prompt requesting a data-based review. Gemini generated natural-language observations and suggestions. Python then saved the generated response as text and as a Word document.

6. Practical Suggestions

1. Keep application statuses and follow-up dates updated.
2. Review applications marked 'Applied' and plan follow-ups where appropriate.
3. Prepare role-specific examples and practise explaining projects, SQL queries, data cleaning and dashboard decisions before interviews.
4. Track outcomes by portal over time. Compare interview and offer rates only when enough records are available.
5. Add more real application records before drawing broader conclusions.

7. Scope and Limitations

This is a small, illustrative dataset of 10 records. Its results are not industry benchmarks and cannot establish resume quality, portal effectiveness or hiring chances. The project does not search live job openings, submit applications, connect to LinkedIn or Naukri, predict selection outcomes, or automatically refresh the Power BI dashboard. AI suggestions are general guidance based on the summaries provided and should be reviewed before use.

8. Conclusion

The project demonstrates a practical analytics workflow: organizing job application data, preparing and querying it, visualizing measures in Power BI, and using Google Gemini AI to produce a written summary with recommendations. It provided hands-on experience with data analytics tools and a Generative AI API integration.
