JOB HUNT TRACKER

Data Analytics Project – AI-Generated Insights Report

FICTIONAL SAMPLE DATA • 1,010 RECORDS

Dataset note

This report analyses a fictional sample dataset of 1,010 job-application records. The records are illustrative and do not represent real applications, interviews, rejections, offers, candidates, or hiring outcomes. The observations describe the sample data only.

1. Dataset overview

Metric	Value
Total application records	1,010
Average listed salary	8.44 LPA

The average salary is the mean of the Salary_LPA values in the dataset. It is not an actual salary received or a confirmed expected salary.

2. Application status distribution

Current status	Records	Share
Applied	425	42.08%
Interview	211	20.89%
Rejected	144	14.26%
Shortlisted	127	12.57%
Offer	52	5.15%
Withdrawn	51	5.05%

Applied is the largest status group (425; 42.08%). 211 records (20.89%) are marked Interview, while 127 (12.57%) are marked Shortlisted. These are separate current-status categories. The Interview count represents application records in Interview status, not interview rounds. The 52 Offer records (5.15%) represent the share of sample rows labelled Offer, not a real candidate's conversion rate.

3. Job portal distribution

Job portal	Records	Share
Indeed	223	22.08%
Company Website	215	21.29%
Internshala	198	19.60%
Naukri	190	18.81%
LinkedIn	184	18.22%

Indeed has the highest record count in this sample (223), followed by Company Website (215), Internshala (198), Naukri (190), and LinkedIn (184). This describes application volume only; it does not identify the best-performing portal. A fair comparison would require portal-specific outcome rates and sufficiently representative data.

4. What the dashboard measures

- Total Applications: count of application records (1,010).
- Status cards and distribution: count of records in each recorded status.
- Average Salary (8.44 LPA): average of the listed Salary_LPA values across the sample.
- Interview status count: 211 application records. If this measure filters status = Interview, label it 'Applications in Interview Status' rather than 'Total Interview Rounds'.

5. Practical suggestions based on the sample

1. Review the 425 records marked Applied and update their status when new information becomes available.
2. Track follow-up dates and record whether a follow-up led to a response.
3. Compare status distributions across job portals using rates as well as counts; do not rank portals by application volume alone.
4. Keep each application's current status clearly defined and consistent.
5. If interview rounds matter, track them separately rather than treating application status as the number of interviews.
6. Use more realistic, validated records before drawing broader conclusions.

6. Scope and limitations

- The dataset is fictional and contains 1,010 illustrative records. Its distributions are not verified labour-market statistics.
- No industry benchmark comparison is included because no reliable benchmark source has been provided.
- The data cannot prove that a resume passes ATS filters, that one portal produces better-quality offers, or that a candidate is highly competitive.
- The status counts do not establish an interview-to-offer conversion rate because the records do not provide verified application-stage history or link interview rounds to offers.
- Gemini generated written observations and suggestions from the supplied data summary. These are AI-generated guidance, not predictions or verified facts.
- The Power BI dashboard and Gemini report are separate outputs based on the job-application dataset. Gemini is not directly connected to or analysing the Power BI dashboard.

7. Conclusion

This project demonstrates a practical data analytics workflow using Excel, Python, SQL, and Power BI, with an additional Google Gemini API integration through Python to generate written observations and suggestions. The dashboard summarises the sample records, while the AI-generated report provides a natural-language explanation of selected patterns. Because the dataset is fictional, the findings are for demonstration and learning purposes only.
